

++

Privilege Escalation

Nick Jones

20th March 2017

++

Who am I?

Nick Jones

- + Security Consultant at MWR InfoSecurity
- + Web Applications and Infrastructure Assessments

Research Topics:

- + Cloud/DevOps
- + Malware Command and Control

++

Who are MWR InfoSecurity?

A global, research-led cybersecurity consultancy

- + Global – 3 UK offices + US, Singapore, South Africa, Poland
- + Research-led – everyone gets research time, even juniors
- + Cybersecurity consultancy – help clients secure their networks, get paid to hack things

++

Why are we Awesome?

Lots of good people, fun place to work

- + Multiple Pwn2Own wins, talks at Black Hat, DEF CON etc

HackFu

- + Annual two-day hacking challenge

MWRICON

- + Annual internal conference – talks and workshops from our consultants

— windows Network Security

++
Research

Amazon Alexa

- + Exposed debug ports +
SD card booting = root

++

Why are we Awesome?

- + Buffer overflow on credit card reader led to...

++

Why are we Awesome?

- + Flappy Bird!
- + Game loads off malicious chip & pin card
- + Insert card, play game

++

What is Privilege?

The level of access that a user or application has

- + The files or data they can read/write
- + The programs they can run
- + The hardware they can interface with

- ++
- ## Why Escalate it?
- Perform actions we're not supposed to
- + Read/write files we currently can't access
 - + Execute programs we currently can't run
 - + Access devices we can't currently communicate with

++ Types of Escalation

Vertical

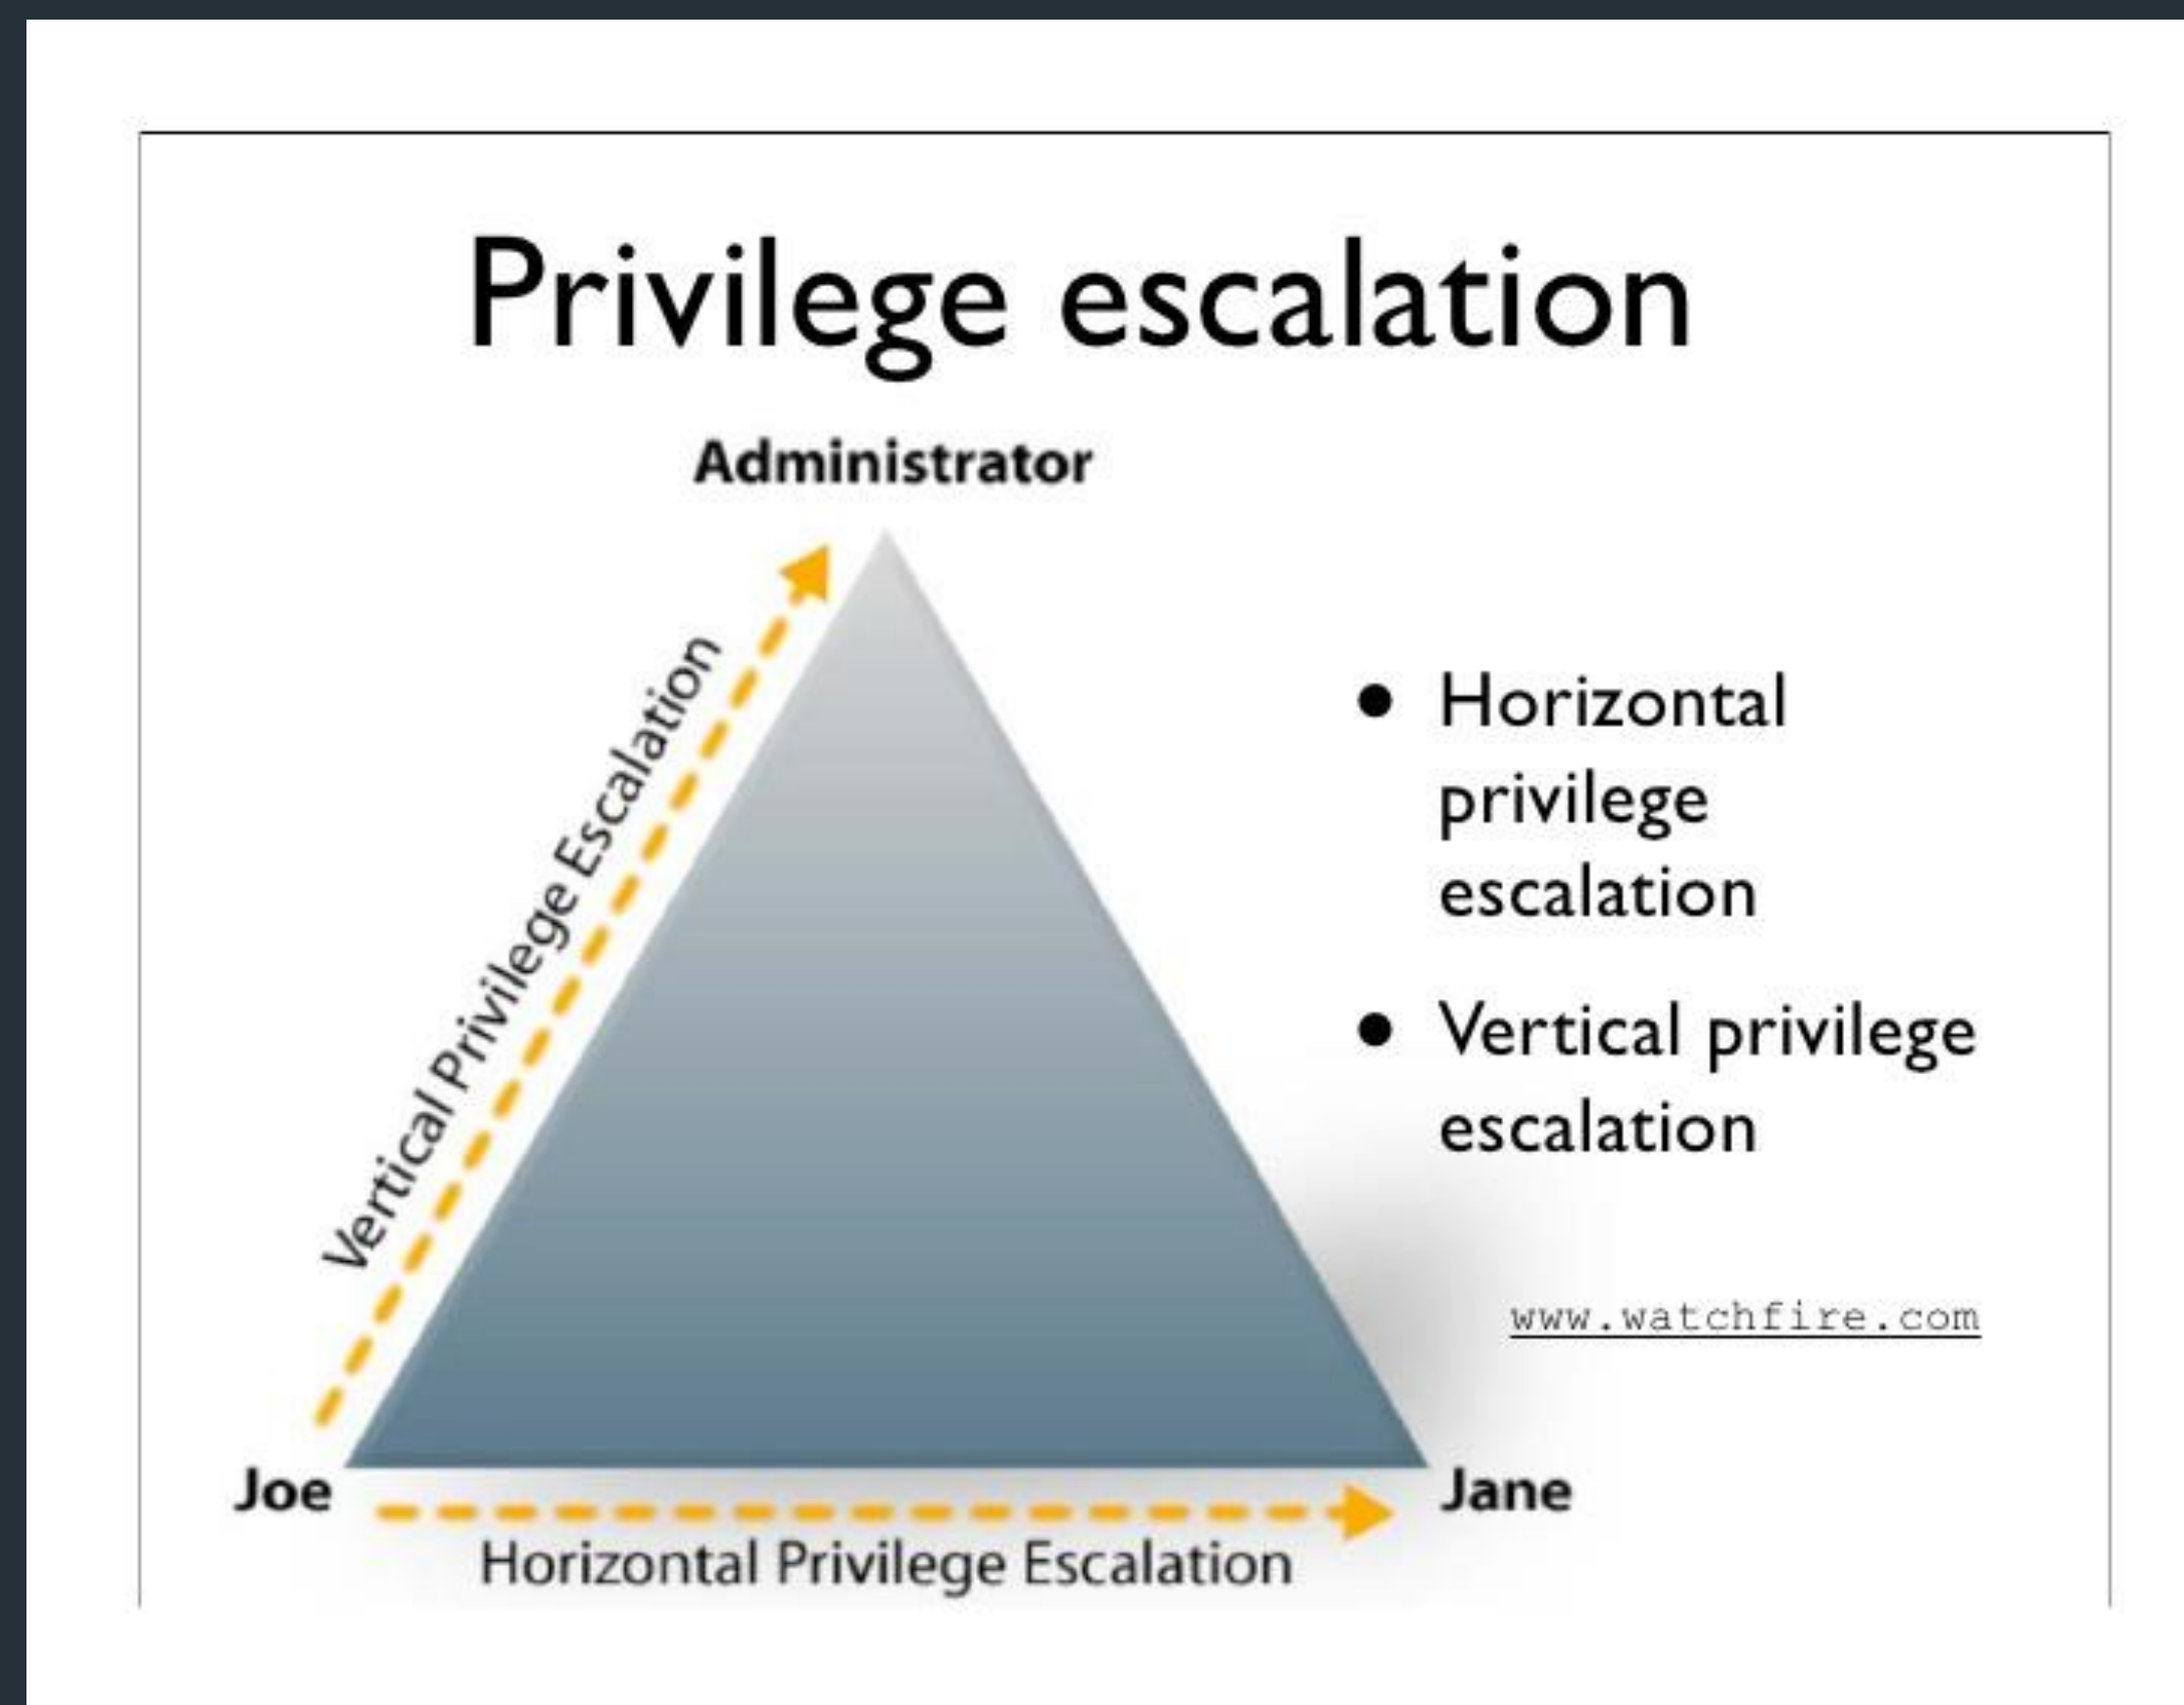

- + Extra privileges
- + Normal user -> admin/root

Horizontal

- + Access rights of a different user the same level

Privilege Escalation

++ Horizontal vs Vertical

- ++
- ## Why Escalate Horizontally?
- + Amazon – purchase on someone else's card
 - + Online Banking – move money around from someone else's account
 - + Student Management Systems – view someone else's grades

More generally, they may have files, emails, etc. containing passwords, or other useful info

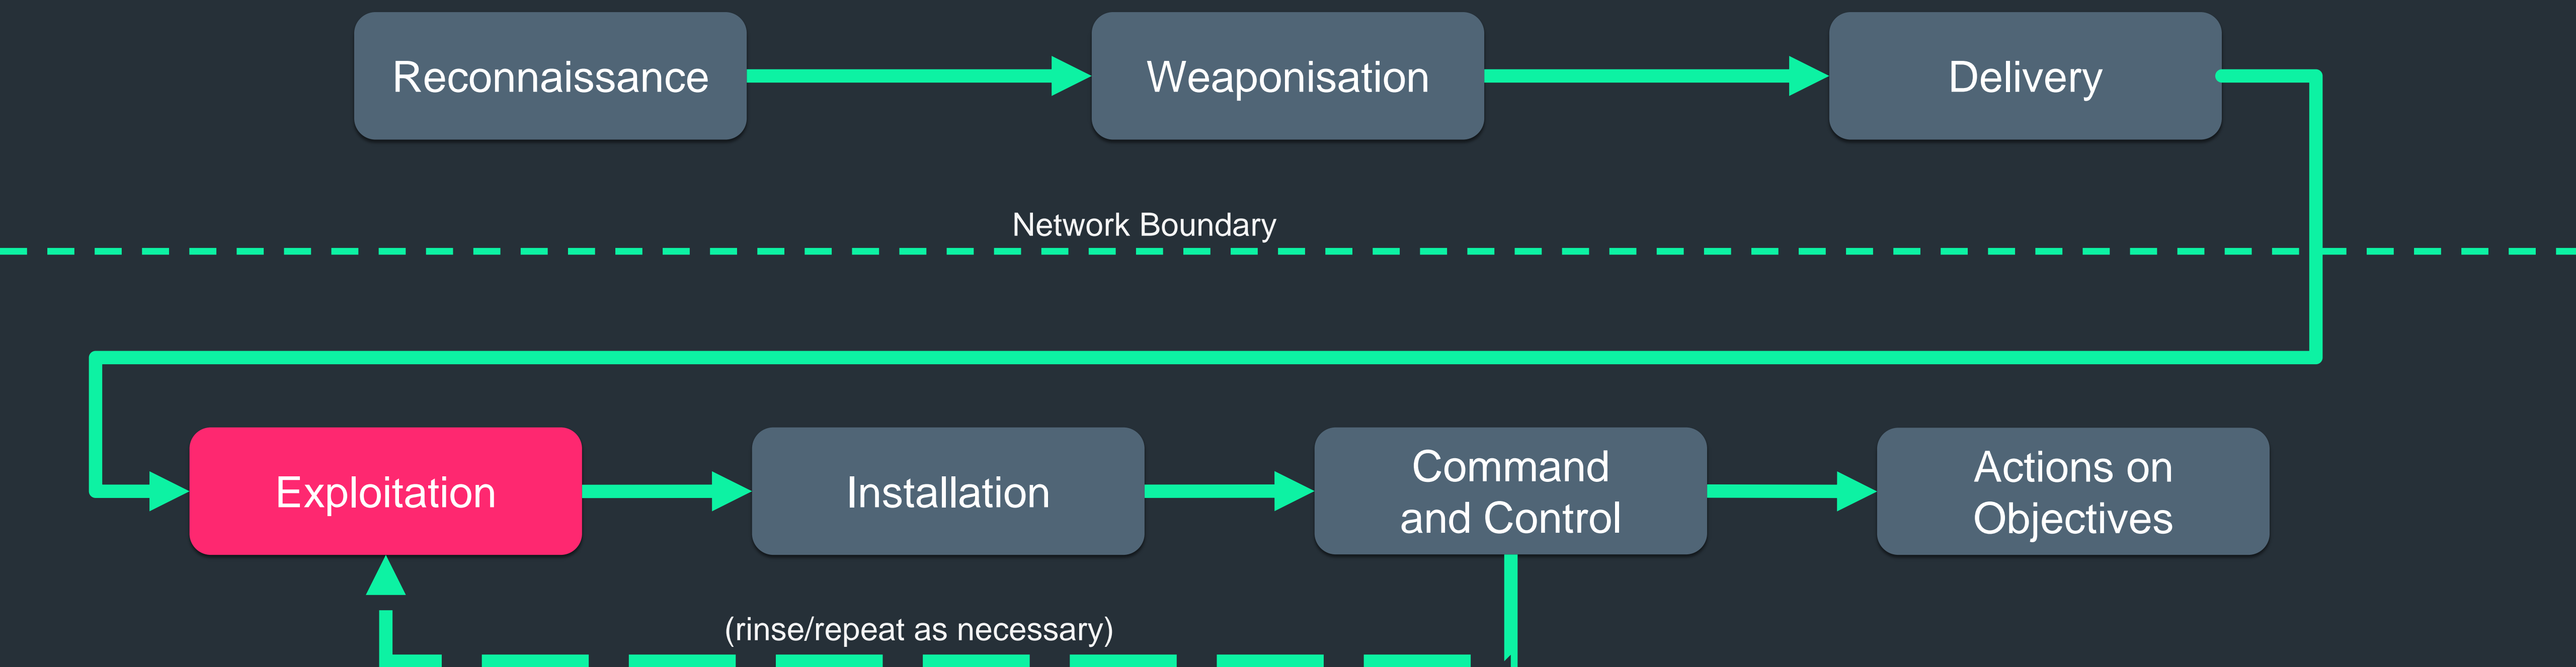

++

Attack Paths – The Cyber Killchain

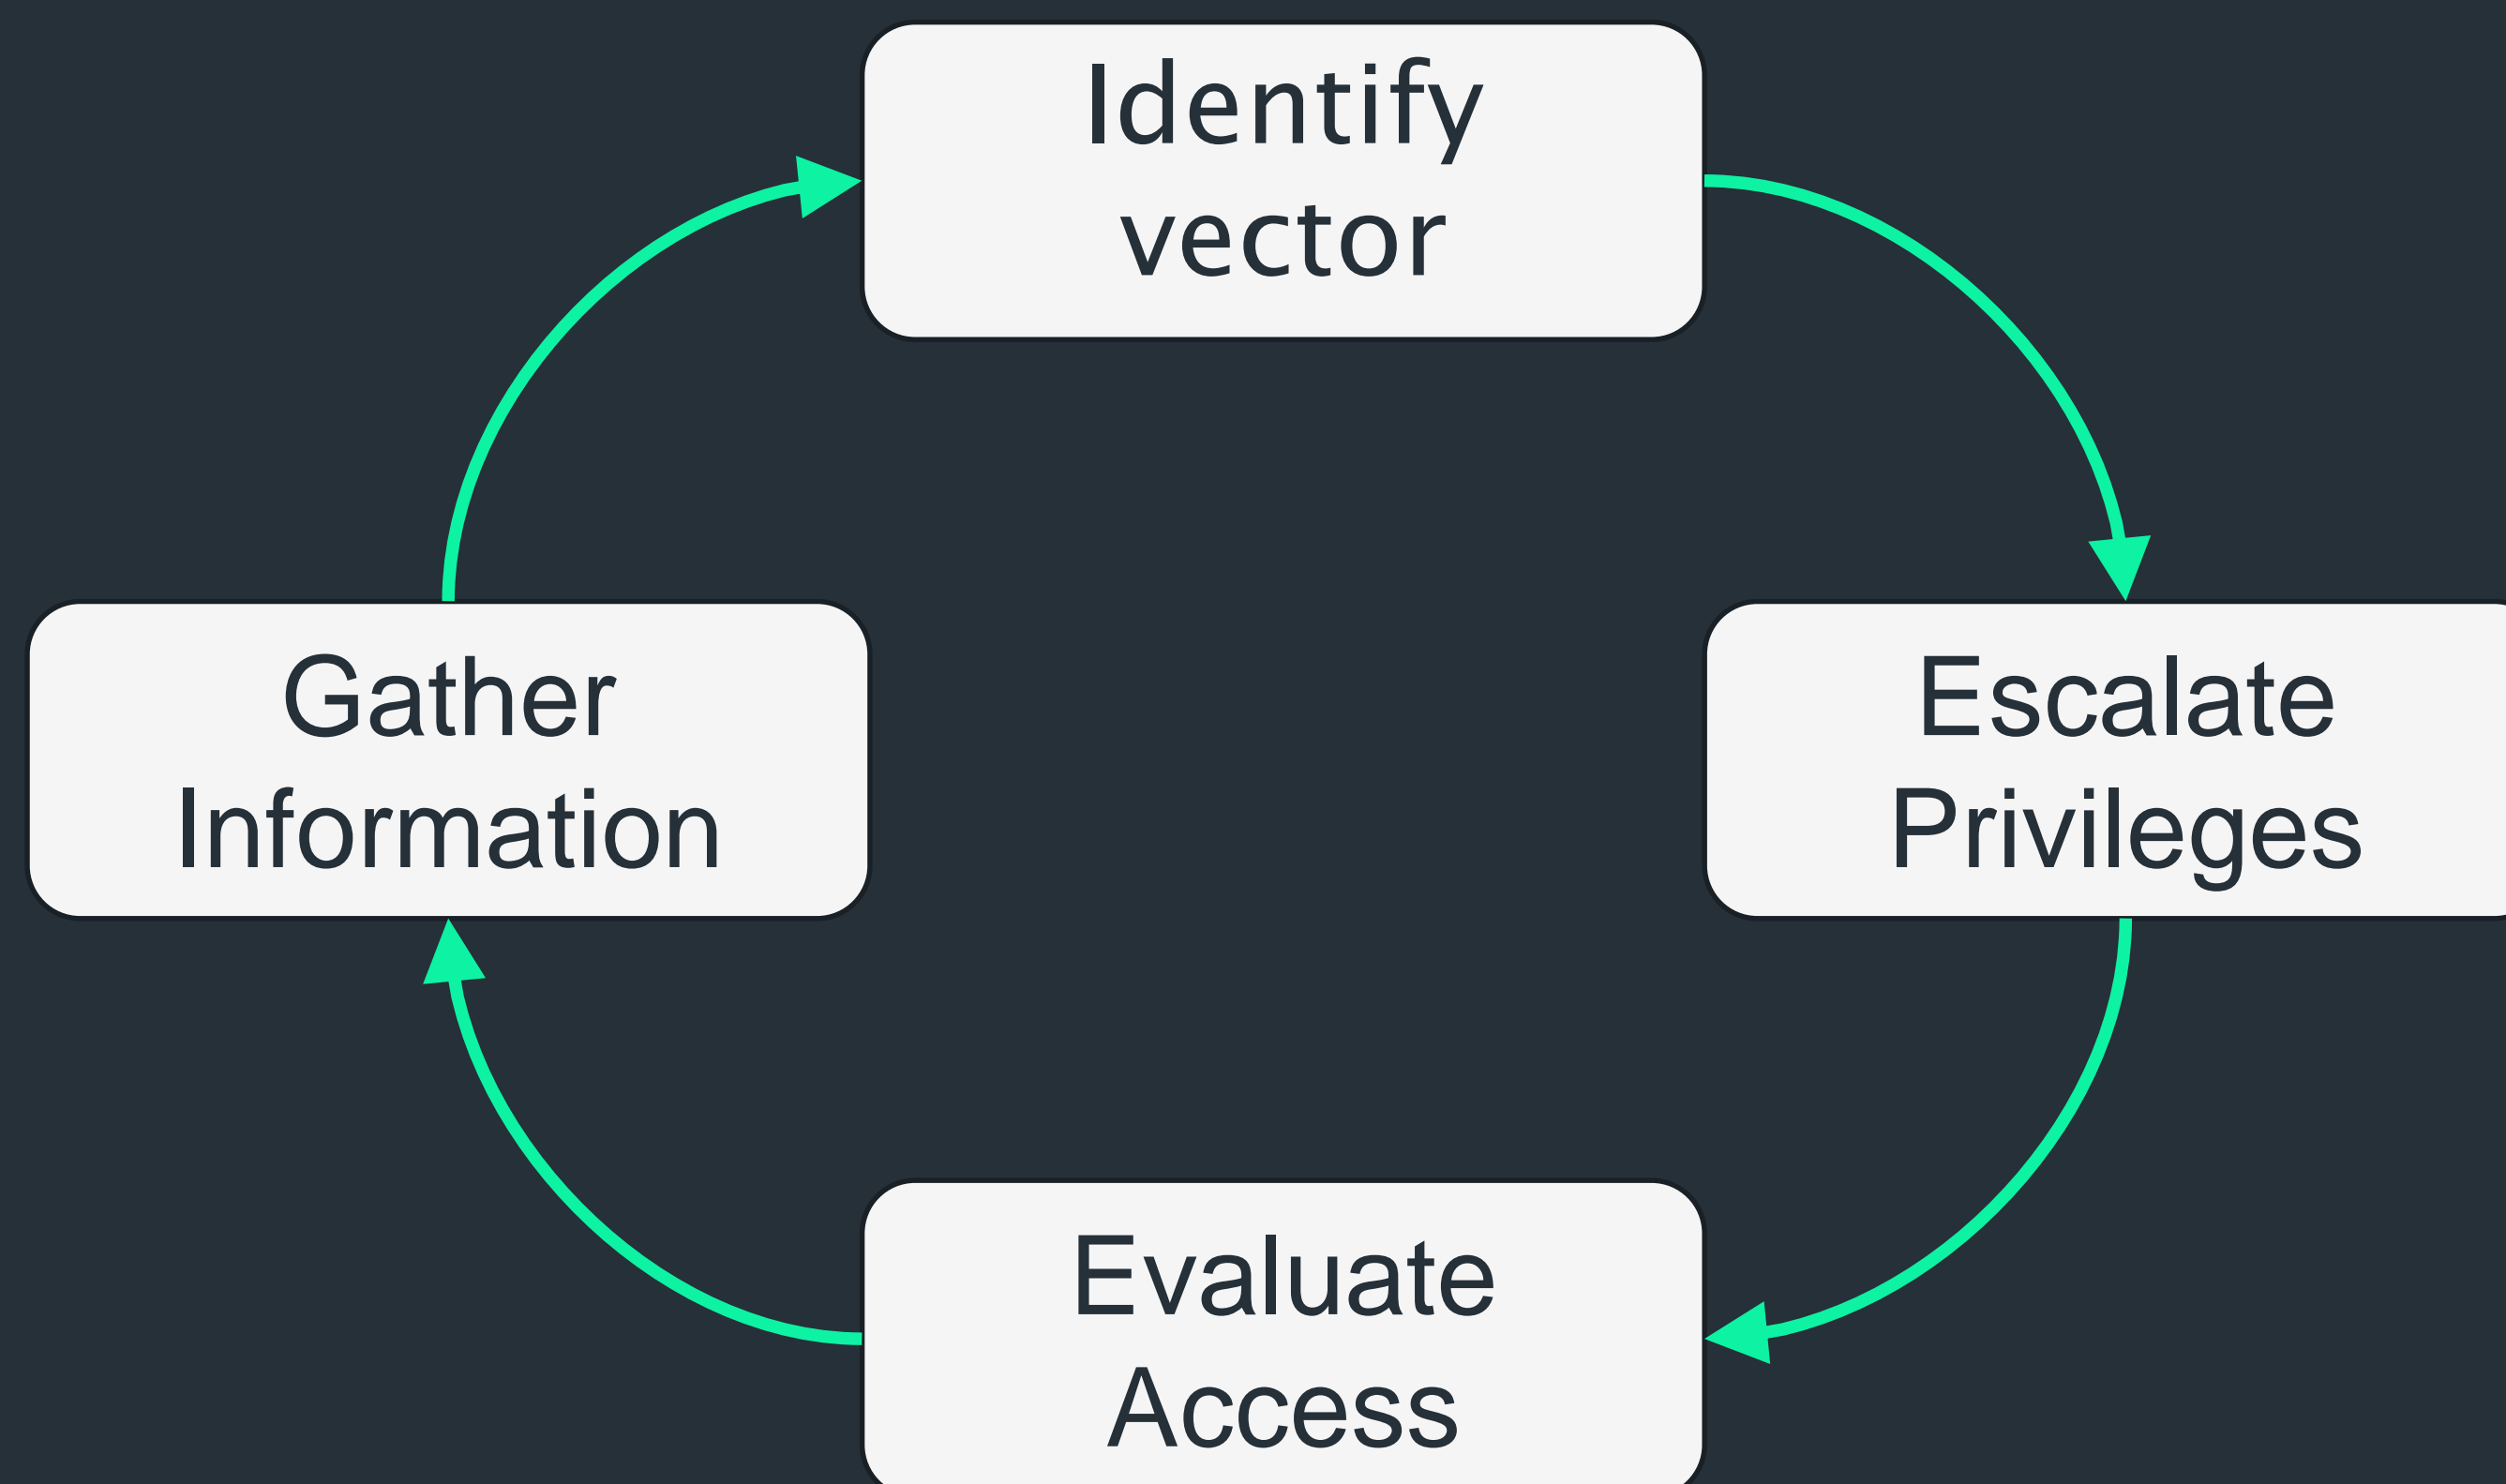

++

Attack Paths – The Cyber Killchain

++
What is the Process?

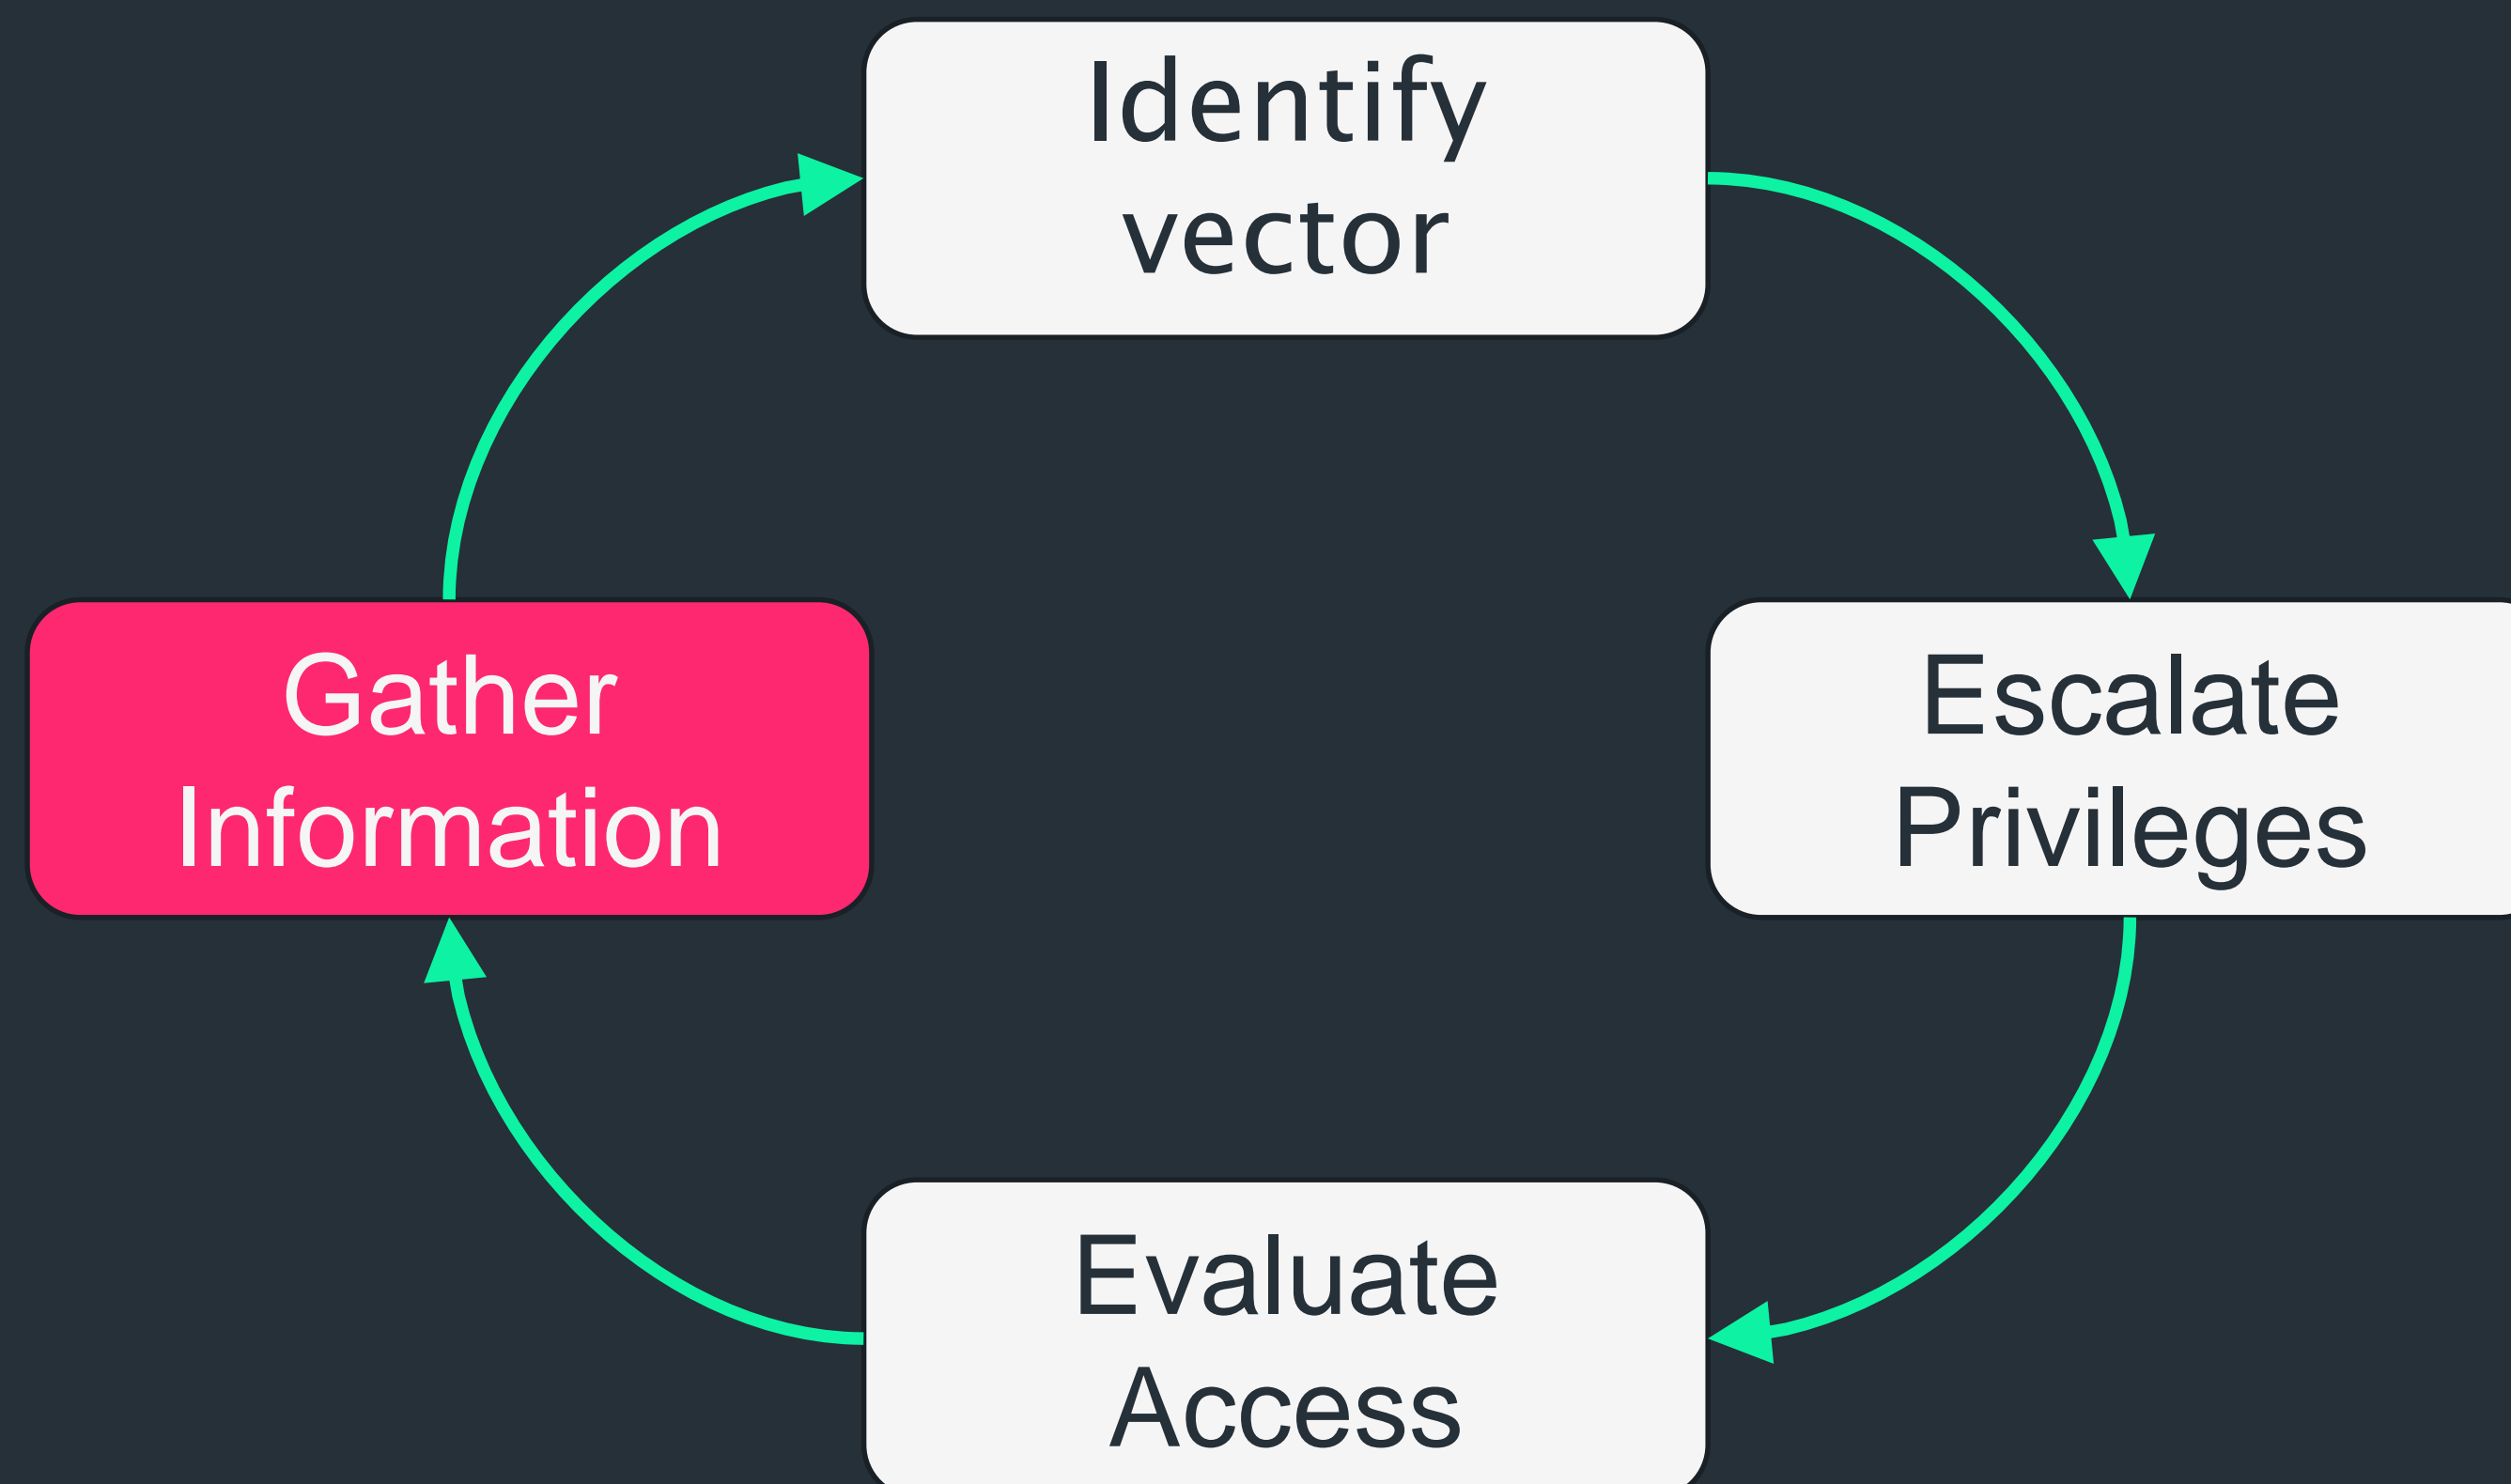

++

What is the Process?

You may need to repeat this process multiple times.

- + Web app: normal user -> app administrator -> root
- + Windows: Low integrity -> local user -> SYSTEM
- + Linux: user -> root -> root on another box

++
What is the Process?

- ++
- ## Gather Information
- + Otherwise known as reconnaissance, or enumeration
 - + Details of the system, software, users, network...
 - + More information -> better chance of finding an escalation vector
 - + What information is useful?

++

What information is useful – Web Apps

A site map

The screenshot shows the Burp Suite interface. The 'Site map' tab is active, displaying a tree view of the website structure. The 'Scope' tab is also visible. The 'Filter' bar indicates that not found items, CSS, image and general binary content, 4xx responses, and empty folders are hidden. The 'Host' column in the table lists various domains, including https://addons.mozilla.org, http://ha.ckers.org, http://mutillidae, and several others. The 'Method' column shows the HTTP method used for each request. The 'URL' column shows the specific endpoint. The 'Params' column shows the parameters passed in the request. The 'Stat...' column shows the status code. The 'Length' column shows the response length. The 'MIME type' column shows the content type. The 'Title' column shows the page title. The 'Comment' column shows any additional comments. The 'Time requ...' column shows the time taken for the request. The 'Request' tab is active, showing the raw request details for the selected request. The request is a POST to /index.php?page=login.php. The headers include Host: mutillidae, User-Agent: Mozilla/5.0 (X11; Ubuntu; Linux i686; rv:33.0) Gecko/20100101 Firefox/33.0, Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8, Accept-Language: en-US,en;q=0.5, Accept-Encoding: gzip, deflate, Referer: http://mutillidae/index.php?page=login.php, Cookie: PHPSESSID=5qsa0his00rqi0b5jee5405d04; showhints=1, Connection: keep-alive, Content-Type: application/x-www-form-urlencoded, and Content-Length: 62. The body of the request is username=admin&password=admin123&login-php-submit-button=Login.

—| Privilege Escalation

++

What information is useful – Web Apps

Technical information

- + What language is it built in?
- + What frameworks have they used?
- + What databases does it communicate with?
- + Are there any perimeter defences (firewalls, WAFs etc)?

MWR
LABS

++ What information is useful? – Windows/Linux

- + Which version of the OS is this?
- + What users are on the system? Who am I currently?
- + Installed software and devices
- + Network information, routing tables, firewall rules etc
- + Services/daemons and their permissions
- + Scheduled Tasks/cron etc.

- ++
- ## Web app reconnaissance tools
- + A web browser
 - + Application help pages
 - + An intercepting proxy – Burp Suite/ZAP/Fiddler
 - + Nmap
 - + Nikto/Arachni/Netsparker/{insert app scanner here}

++

Windows reconnaissance tools

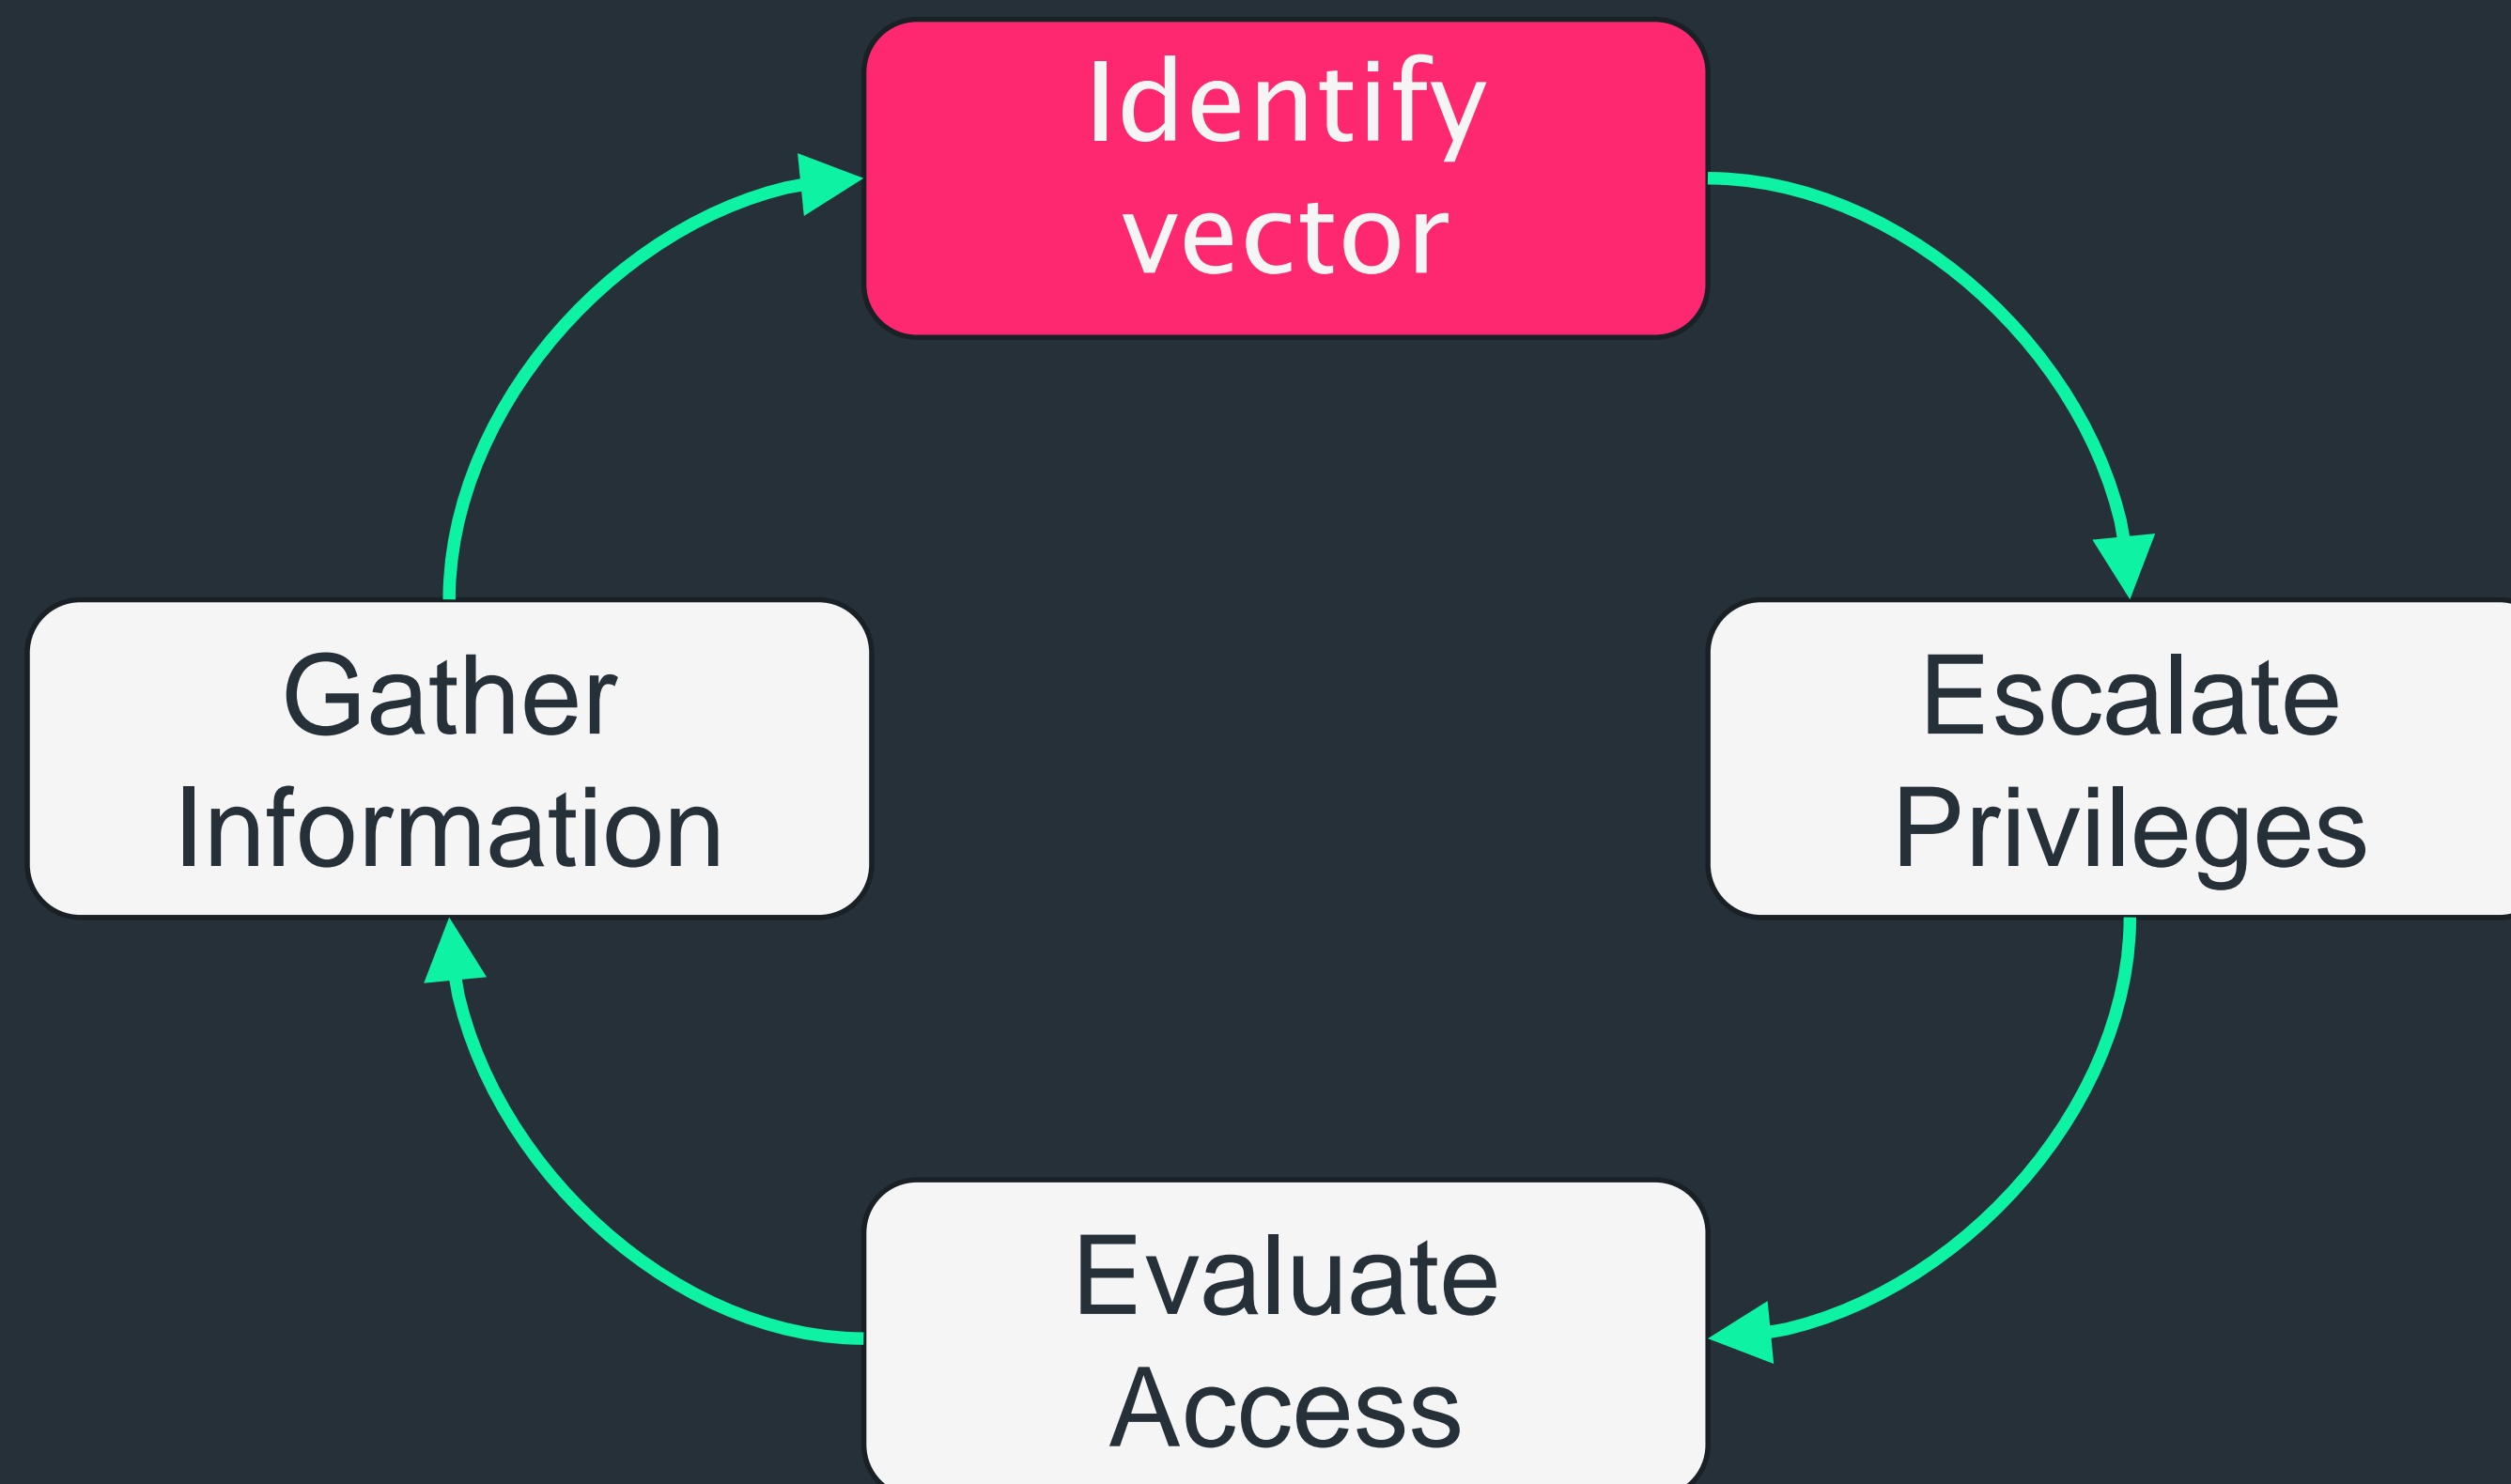

- + Native windows commands/GUI components – systeminfo, net, netstat, tasklist, services.msc...
- + WMIC
- + PowerSploit's PowerUp modules
- + Metasploit's Windows Post-Exploitation Modules
- + Sysinternals Suite
- + Windows-exploit-suggester / windows-privesc-check

++

Linux reconnaissance tools

- + Native Linux commands – service/init.d, ps, netstat...
- + Digging through log/config files – /etc/passwd, .bash_history, service config...
- + Metasploit's Linux Post-Exploitation Modules
- + Linuxprivchecker.py
- + LinEnum
- + Unix-privesc-check

++
What is the Process?

++

Identify escalation vector

Review gathered information, identify your options

Pick a vector based on your requirements

- + Test Environment? Pick the easiest
- + Production environment? Pick one that won't break things
- + Need to be stealthy? Pick something that'll blend in

++

Examples of Escalation Vectors

- + Authorisation bypasses
- + Poor passwords / password reuse
- + Misconfiguration
- + Exploits
- + Design flaws

++

Authorisation bypasses

Escalate by accessing privileged content, without the necessary rights

- + Direct object referencing
- + Admin:true in a web cookie
- + Interacting with Android app IPC endpoints that should be locked down

++

Poor Passwords/Password Reuse

Guess or crack an account's passwords, try passwords you've found elsewhere

- + Pa55w0rd on a windows domain admin account
- + Use XSS to Keylog someone's credentials, password also used on their email account
- + Password spraying – try a known or common user/password on other systems
- + Brute-force – guess until you find it, last resort

++

Misconfiguration

Someone's misconfigured a service, file permissions, server hardening features...

- + Windows: No software restriction policies, unquoted service paths, permissive service configurations...
- + Linux: suid files, writeable authorized_keys files, readable private keys, cron jobs with world writeable scripts...

++ Exploits

Poorly written code → privilege escalation

- + Not just in apps, check OS, libraries in use, etc.
- + Jailbreaks are a form of exploit-related privilege escalation
- + Be careful here – exploits often unstable, may crash apps/systems

++

Design Flaws

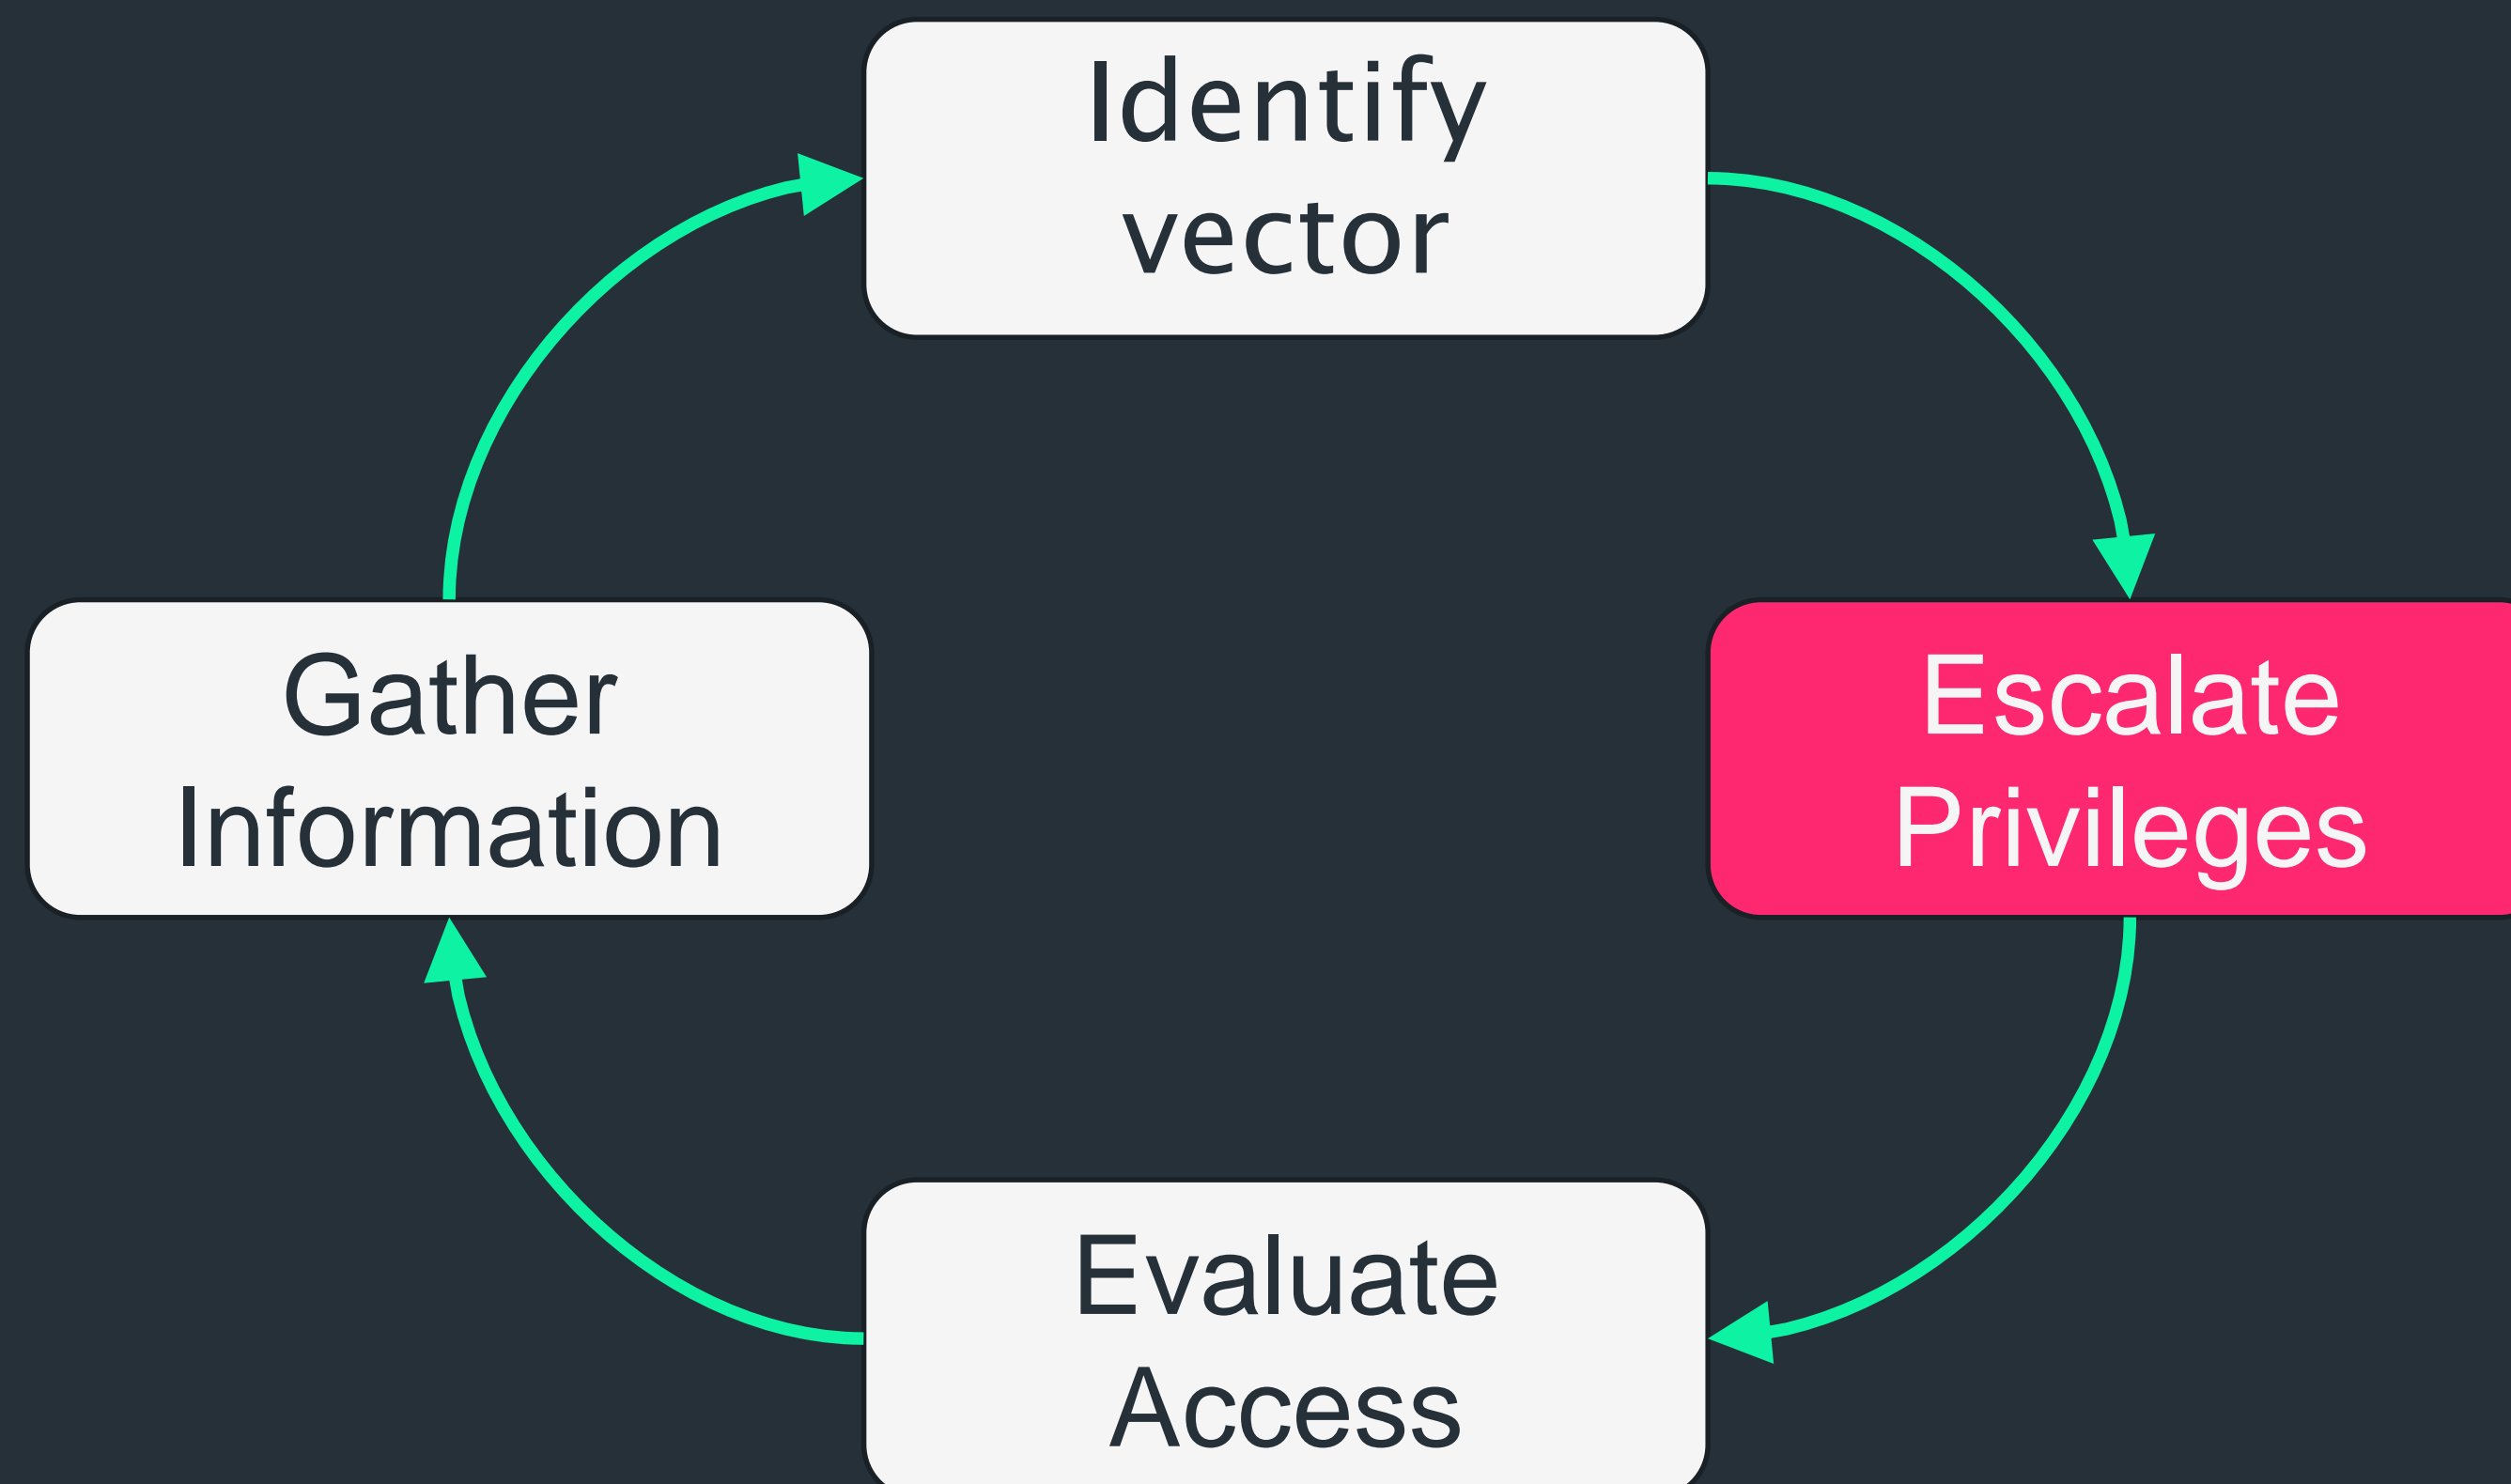

Flaws in the design of applications and protocols

- + Hard to patch
- + Usually low-risk

Great example from one of our interns

- + Unintended feature in Microsoft Exchange ActiveSync
- + Valid email account → read from any file share on an internal network

++
What is the Process?

++ Escalate

Exploit the identified vectors

Important to consider potential side effects

- + If exploiting a code bug, will this crash the app?
- + If trying to be stealthy, will this be spotted by EDR, threat hunters or incident responders?

++

Escalate – Examples

Launch the privilege escalation attack

- + Use an authorisation bypass
- + Log in with a cracked password
- + Run an exploit
- + Alter a windows service to run a malicious binary

++
What is the Process?

++

Evaluate Access

Do you have the access you wanted?

- + If yes, game over
- + If not, repeat the process

++

Modern Enterprise Networks

- + Thousands of endpoints
- + Hundreds of servers
- + Mobile Devices
- + VPNs
- + Custom Apps

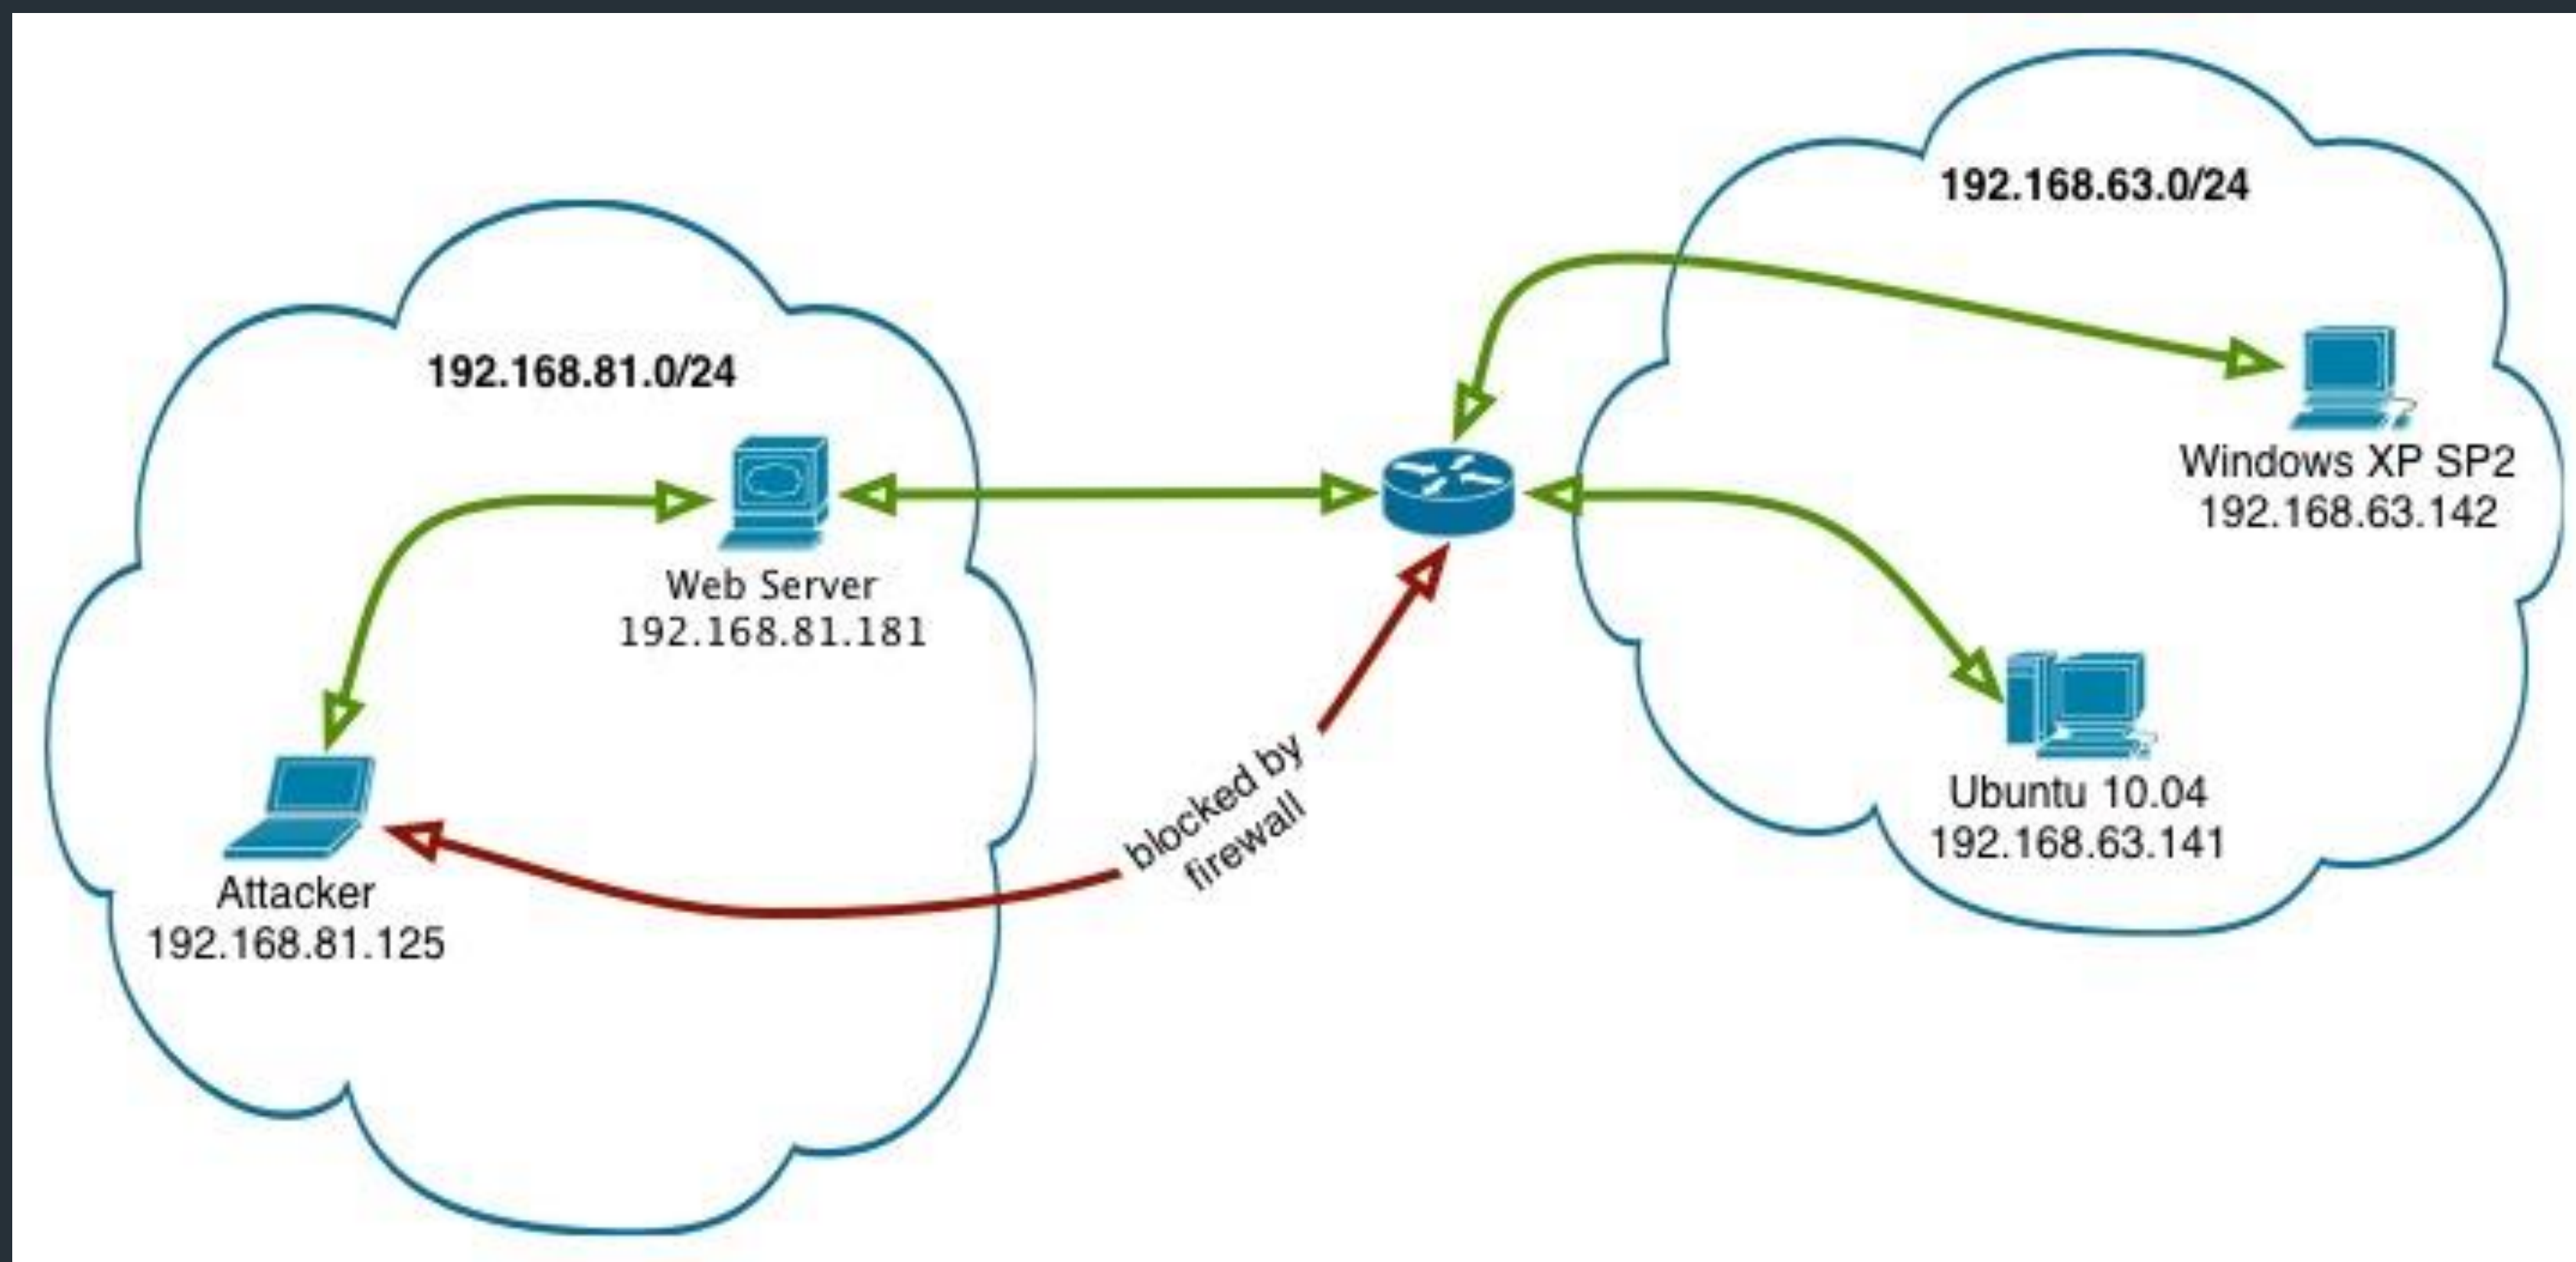

++

Modern Attacks

- + Sophisticated attacks are usually objective-based
- + Compromising one system is rarely enough
- + Escalate across multiple systems or applications
- + Pivot between systems to gain greater access

Privilege Escalation

++ Pivoting

++

Pivoting Techniques

Tunnel over:

- + VPN
- + SSH – port forwarding or SOCKS proxy
- + HTTP CONNECT proxy
- + ...

++

Escalation in Windows Domains

Active Directory

- + Centralised management for windows networks
- + Domain controller – server controlling authentication/authorisation
- + Domain admin – Admin on all systems within the domain

++

Get Domain Admin, ???, Profit!

- + Identify domain admin accounts
- + Find active domain admin sessions
- + Gain administrative access on those systems
- + Steal their credentials or tokens

++

Identifying Target Users and Systems

Can be done manually

+ Net user – find domain admins

```
net user "domain admins" /domain
```

+ Net view – find all machines in the domain

```
net view /domain
```

+ netsess.exe – who's logged in on a machine?

```
netsess.exe \\<host>
```

++

PowerView

Automates most of this

- + Invoke-CheckLocalAdminAccess – Check if user is local admin on specified machine
`Invoke-CheckLocalAdminAccess -ComputerName sqlserver`
- + Invoke-UserHunter – Find where a user's logged in
`Invoke-UserHunter -Username "John Smith"`
- + Invoke-UserHunter – Find all domain admin sessions where current user has admin access
`Invoke-UserHunter -CheckAccess`

++ Bloodhound

Enumerate windows domains and identify multi-hop paths to domain admin automatically

- + Collect data with the powershell ingestor
- + Load collected data into Bloodhound
- + Review graph for escalation routes

Privilege Escalation

++

Pass-The-Hash

Some Windows Protocols allow authentication via hash rather than passwords

1. Compromise host
2. Acquire hashes
3. Transmit hashes as part of authentication requests to services using NTLM authentication

++
Pass-The-Hash

++ Credential Theft – Mimikatz

“A little tool to play with Windows security”

Mimikatz can dump passwords from different sources:

- + Terminal Services
- + Wdigest
- + Kerberos (Domain Authentication)
- + Windows Live

++

Credential Theft – Mimikatz

“A little tool to play with Windows security”

- + Extract plaintext passwords, hashes and Kerberos tickets from memory.

```
mimikatz(powershell) # sekurlsa::logonpasswords

++

Escalation in Windows Domains

- + In this example, accounts are always admin on target system
- + If not? Escalate your privileges on each system.
